

# Instream Flow Issues & Opportunities

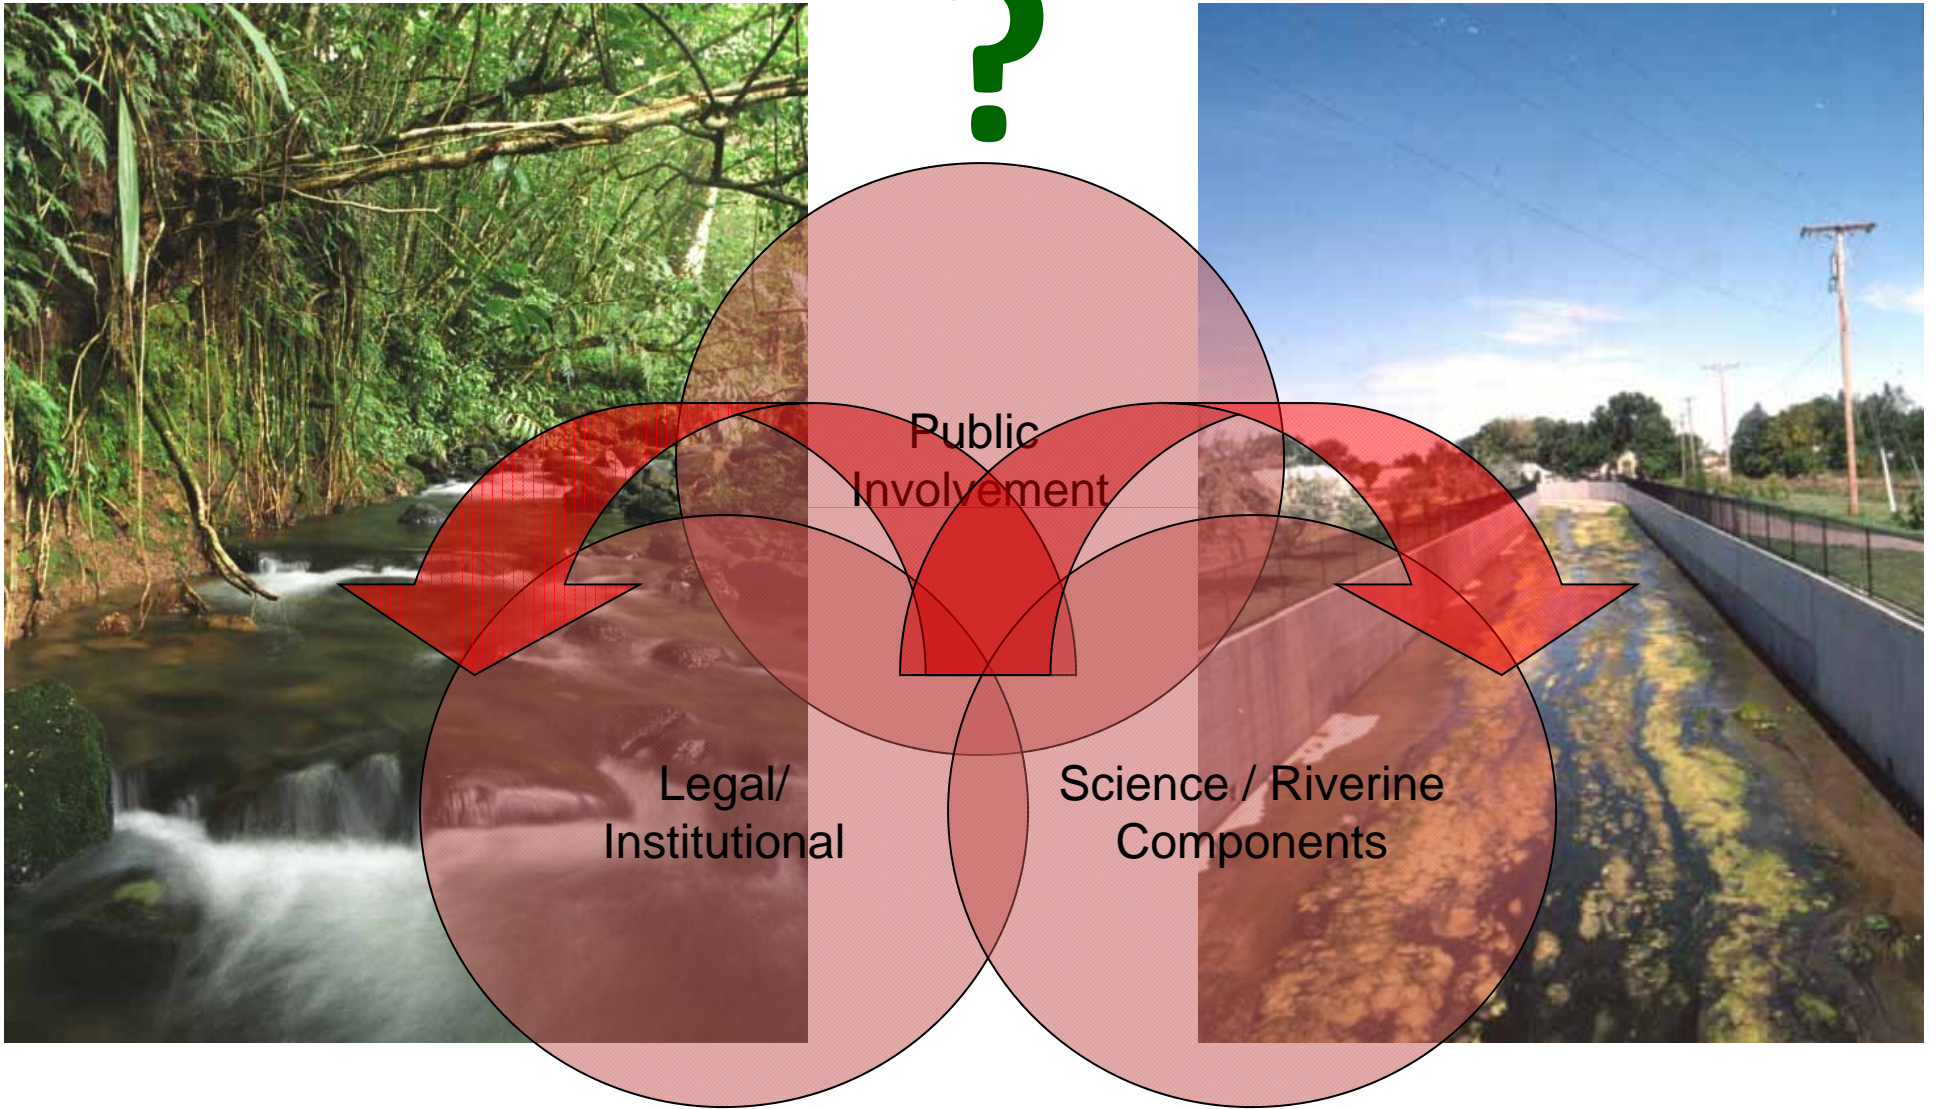

Tom Annear  
Wyoming Game and Fish Department

- 
- **Instream flow perspectives**
  - **Definitions & concepts**
  - **The science of instream flow**
  - **Challenges and opportunities**

How we integrate each element affects how the world looks and our quality of life.

## Projected Upper Colorado River Flows vs. Population Growth in Major Lower Basin Metropolitan Areas

Source: McCabe and Wolock 2007

Achieving maximum beneficial use of water involves more than building “buckets and pipes” and delivering commodities.

The value of water is measured by the full range of functions it provides.

# These Benefits Are Broadly Termed 'Ecosystem Services'

# Finding Balance is a Matter of Value

**Valuation**, in practice, involves some of the oldest problems in economics – revealing and aggregating preferences and addressing uncertainties

Values are perpetually evolving

*from Daily et al. 2000*

# Instream Flows Play a Key Role

(that's not always recognized)

# Instream Flows Myths

- Water needs to be diverted
- Costs too much to measure
- Will cause streams to go dry
- Will impact interstate compacts
- Will stop economic development
- Need dams to get an instream flow
- A gov't. plot to take back water rights
- That won't work in (fill in state name)

# Instream Flow in Wyoming

A scenic landscape photograph of a mountain valley. In the foreground, a river flows through a valley with sparse vegetation and some snow patches. The middle ground shows rolling hills and a small cluster of evergreen trees. In the background, a range of mountains with snow-capped peaks stretches across the horizon under a clear blue sky.

# 41 Years of History

- First application submitted in 1969
- Denied by State Engineer in 1972
- 17 failed laws from 1974 to 1985
- Successful legislation in 1986
- 100<sup>th</sup> instream flow filing in 2006

# What's Happened in Wyoming Since 1986?

- Protected habitat in >100 stream segments (with current day priority dates)
- Essential for permitting new dams
- Stayed off petitions to list 4 native species as T&E
- Used state law to protect water for Wild & Scenic River (vs. federal reserved water right)

# What Hasn't Happened in Wyoming Since 1986?

- No one's lost a water right
- Economy is stronger than ever
- There's been no call for regulation
- 98% of streams are still unprotected
- No dams built to provide an instream flow
- Compacts and decrees have been unaffected
- No controversy over any ISF filing once issued

# Definitions and Concepts

# Instream Flow Can Mean:

Water in the creek but no regulatory mechanism

Enforceable regulatory mechanism but no water

Water in the creek that's protected by an enforceable regulatory mechanism

A little water, some of the time?

All the water, all the time?

# A seasonally adjusted flow regime?

# Protection or Restoration?

## Flow Protection

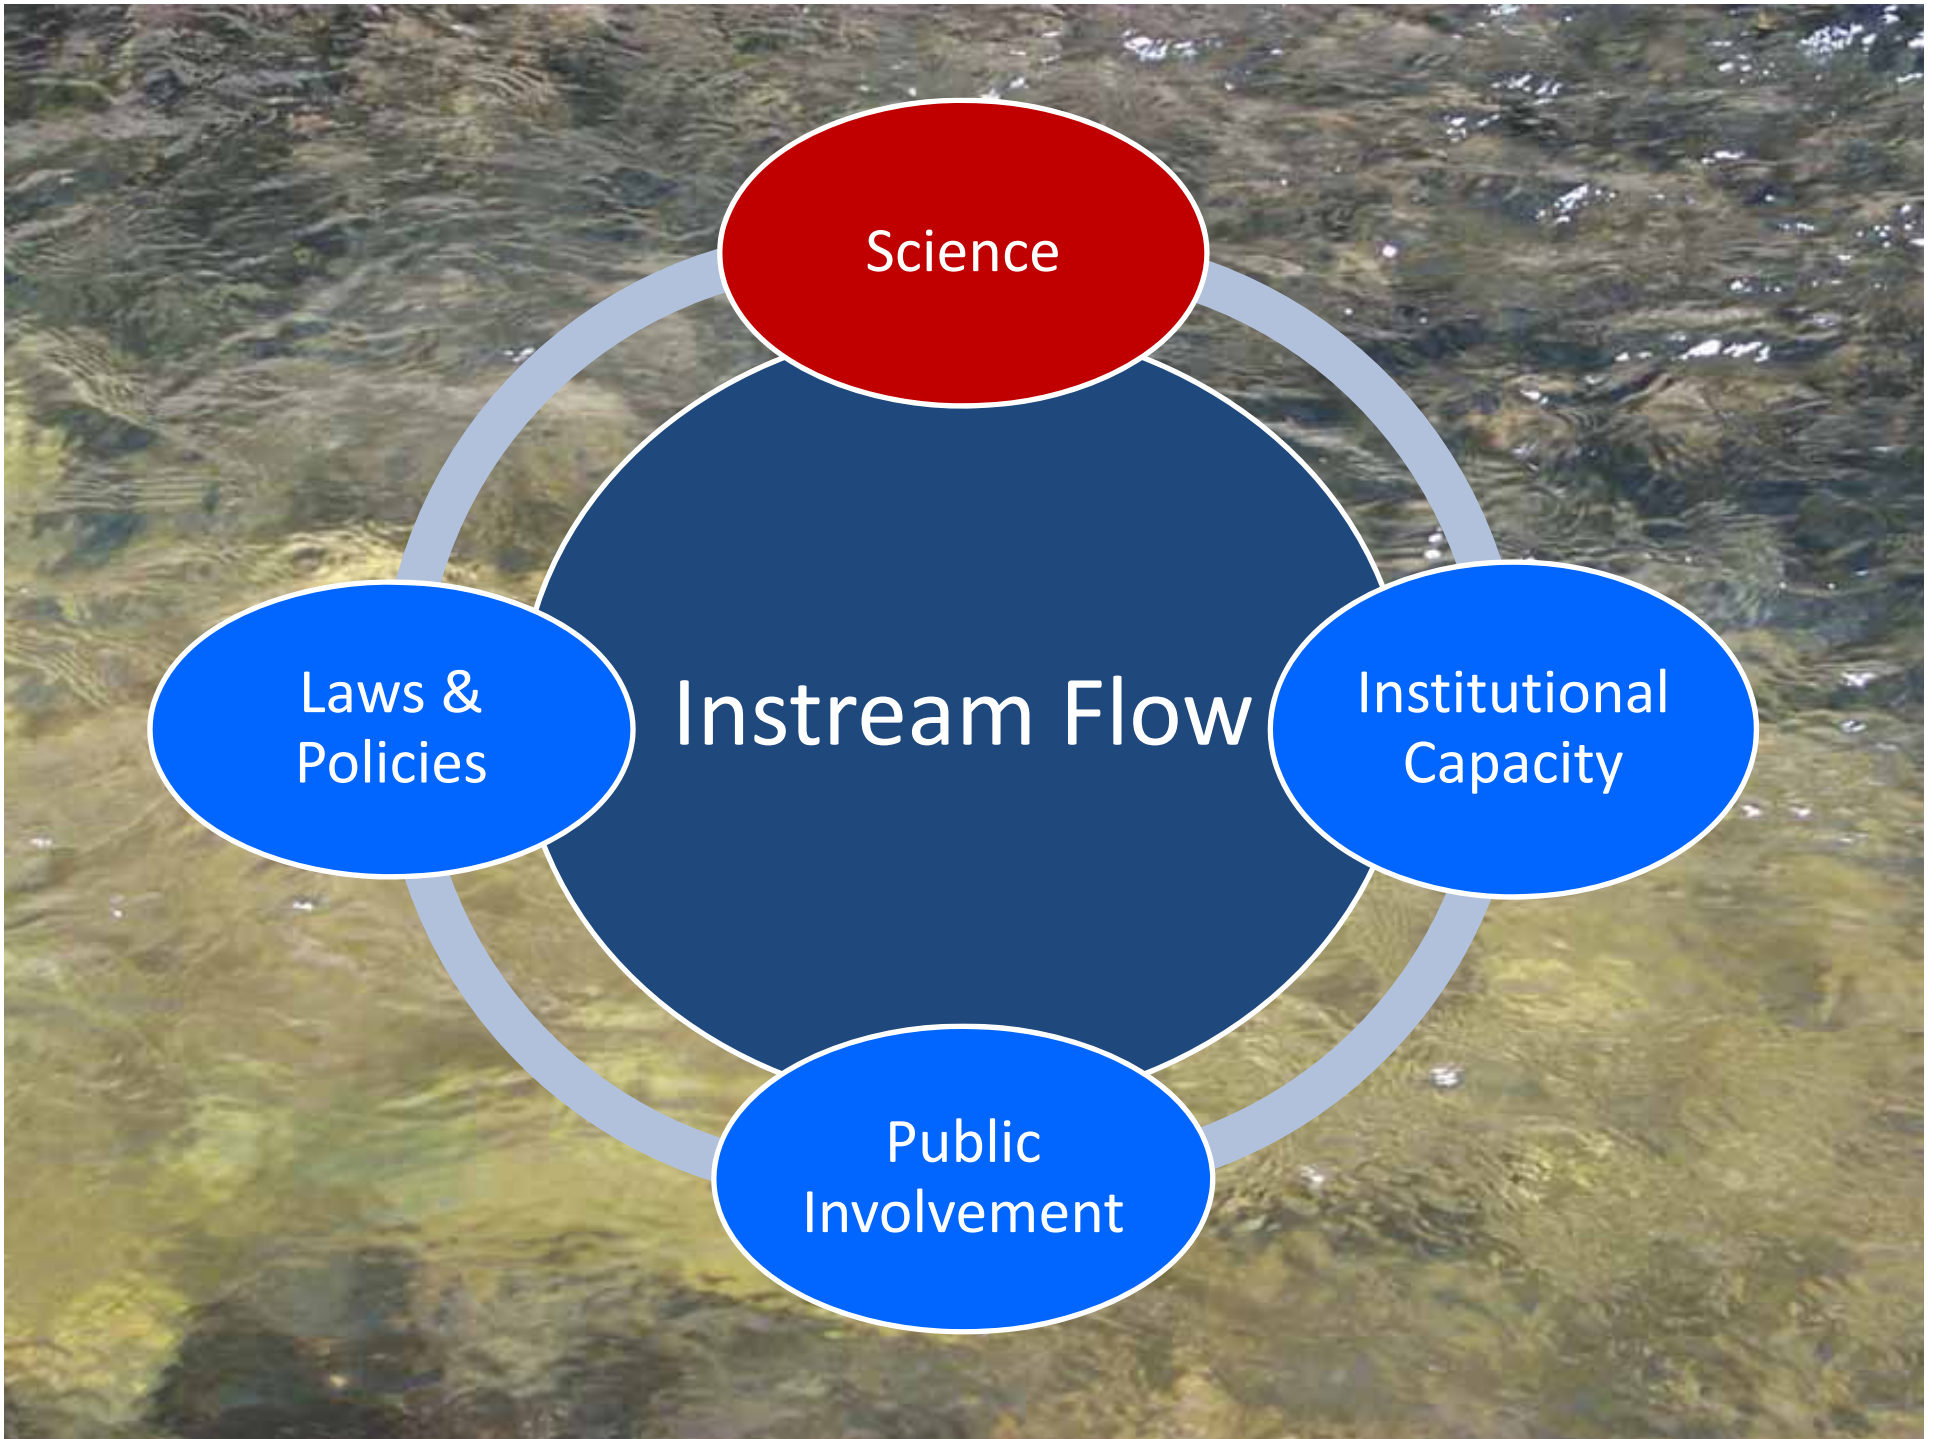

- *Upside Down Instream Flow*
- *Water is usually available*
- *Public land issue*

# Flow Restoration

- *Bottom up instream flow*
- *Need to find water*
- *Private land issue*

Science

Laws &  
Policies

Instream Flow

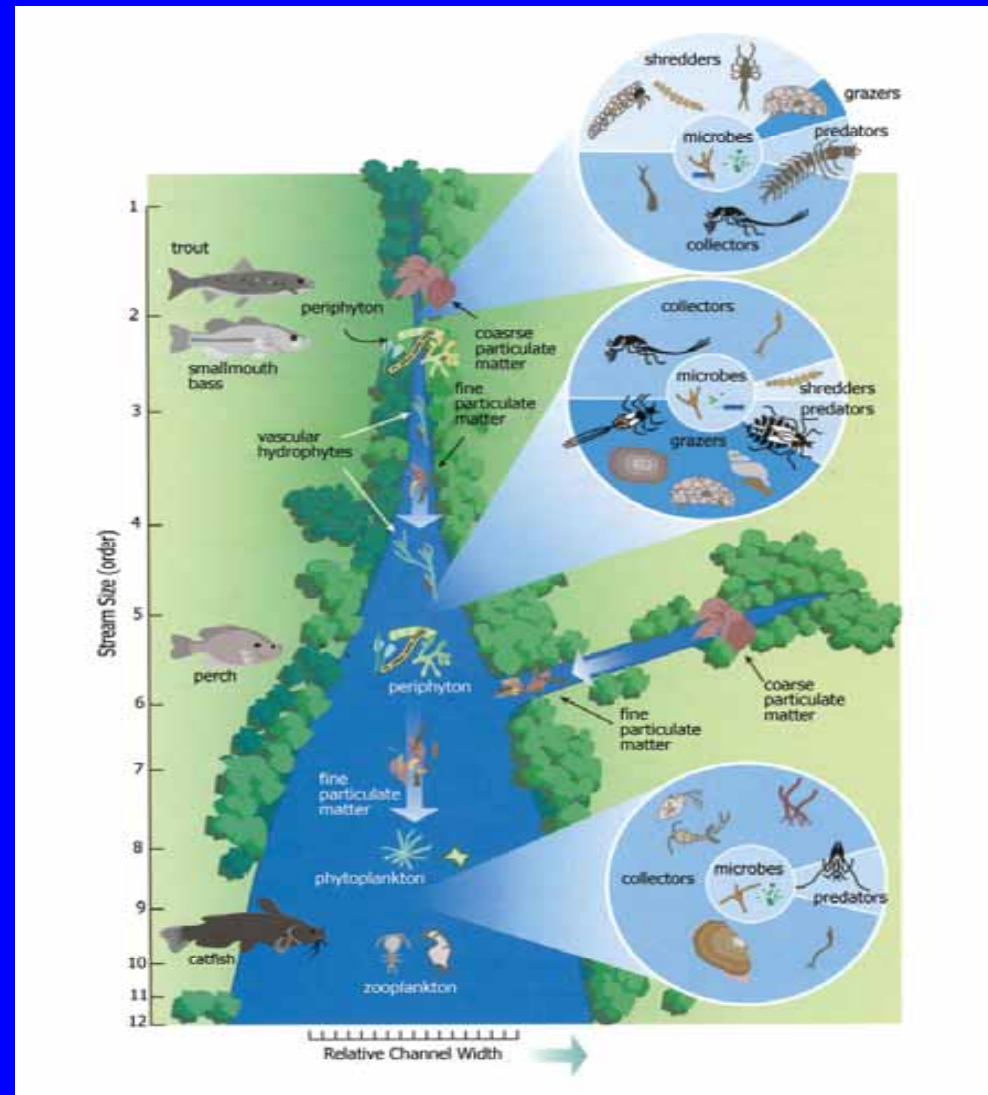

Institutional  
Capacity

Public  
Involvement

# Each Situation is Unique

Rivers and the species that live there change in predictable ways over distance.

# Models tell us about:

- **Hydrology**
  - Short and long-term water availability
- **Biology**
  - Short-term physical habitat availability
- **Geomorphology**
  - Long-term trends of channel conditions
- **Connectivity**
  - Multiple elements and concepts
- **Water quality**
  - Short and long-term

# Habitat Modeling Caveats

- Models manage uncertainty – won't eliminate it.
- Relationship between flow & habitat isn't linear.
- A flow that's good for one species may be detrimental to others.
- There isn't a single "best" flow – think flow regimes.

# Defining nature is a major limitation

0 – Original nature (wilderness)

1 – That nature which is perceived and described;

2 – The nature configured in laboratories or models;

3 – The nature constrained by laws & policies.

*Adapted from Kull (1998)*

# Not Preservationism

- Healthy ecosystems and economies are linked (goal = maximize ecosystem services).
- Fine tune legal & institutional opportunities.
- We are, after all, human – and we want it all.

# Geomorphology

# Biology

# Hydrology

# Connectivity

# Water Quality

# Hydrology

*River systems were built and are maintained by different magnitudes of discharge occurring over time and space. (Hill et al. 1991)*

# Maximum flow

*The problem with minimum flows . . .*

# Hydrology Considerations

- Methods rely on flow statistics
- Don't identify incremental trade-off's and
- Are not linked to riverine form and function
- Need other tools to assess needs for other flow elements

# Biology

Biology also embraces other aquatic organisms in the stream . . .

and the riparian corridor

# Biology Considerations

- Methods focus on fish habitat
- Poor link between habitat and number of fish – unrealistic to expect one
- Need other tools to assess needs for other flow elements

# Geomorphology

# Geomorphic condition is a function of:

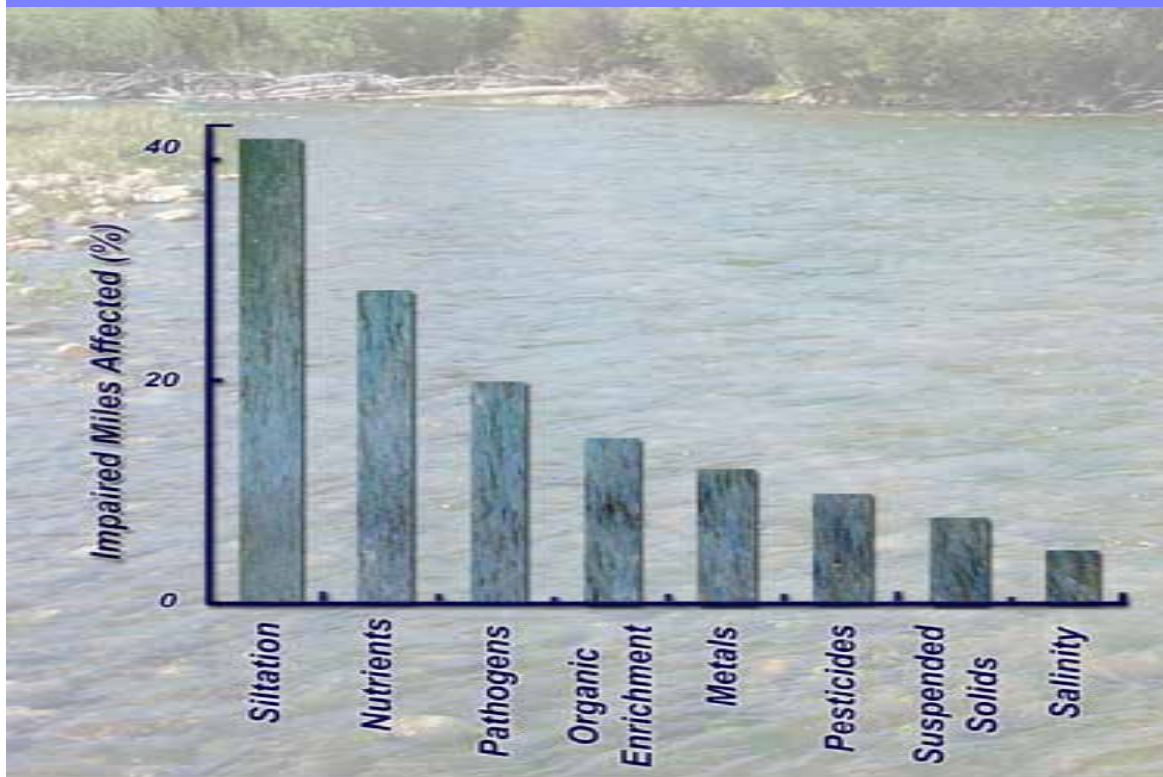

- Sediment addition or removal
- Flow addition or removal
- Channel form (alteration)

# Geomorphology Considerations

- Address long-term physical habitat processes (not tied to species)
- Need to specify timing, duration, ramping
- Need other tools to assess needs for other flow elements

# Water Quality

Pollutants

Temperature

# Water Quality Considerations

- Methods focus on minimum flows
- Don't identify ecological trade-offs
- Need other tools to assess needs for other flow elements

# Connectivity

## The Four Dimensional View of Rivers

*(Adapted from Ward 1989)*

# Connectivity isn't just about fish

- **Nutrients & minerals**
- **Woody material**
- **Bedload**

# Connectivity Considerations

- Few good models to directly address all connectivity elements.
- Specify time and duration when needed
- Need other tools to assess needs for other flow elements

# Holistic Methods

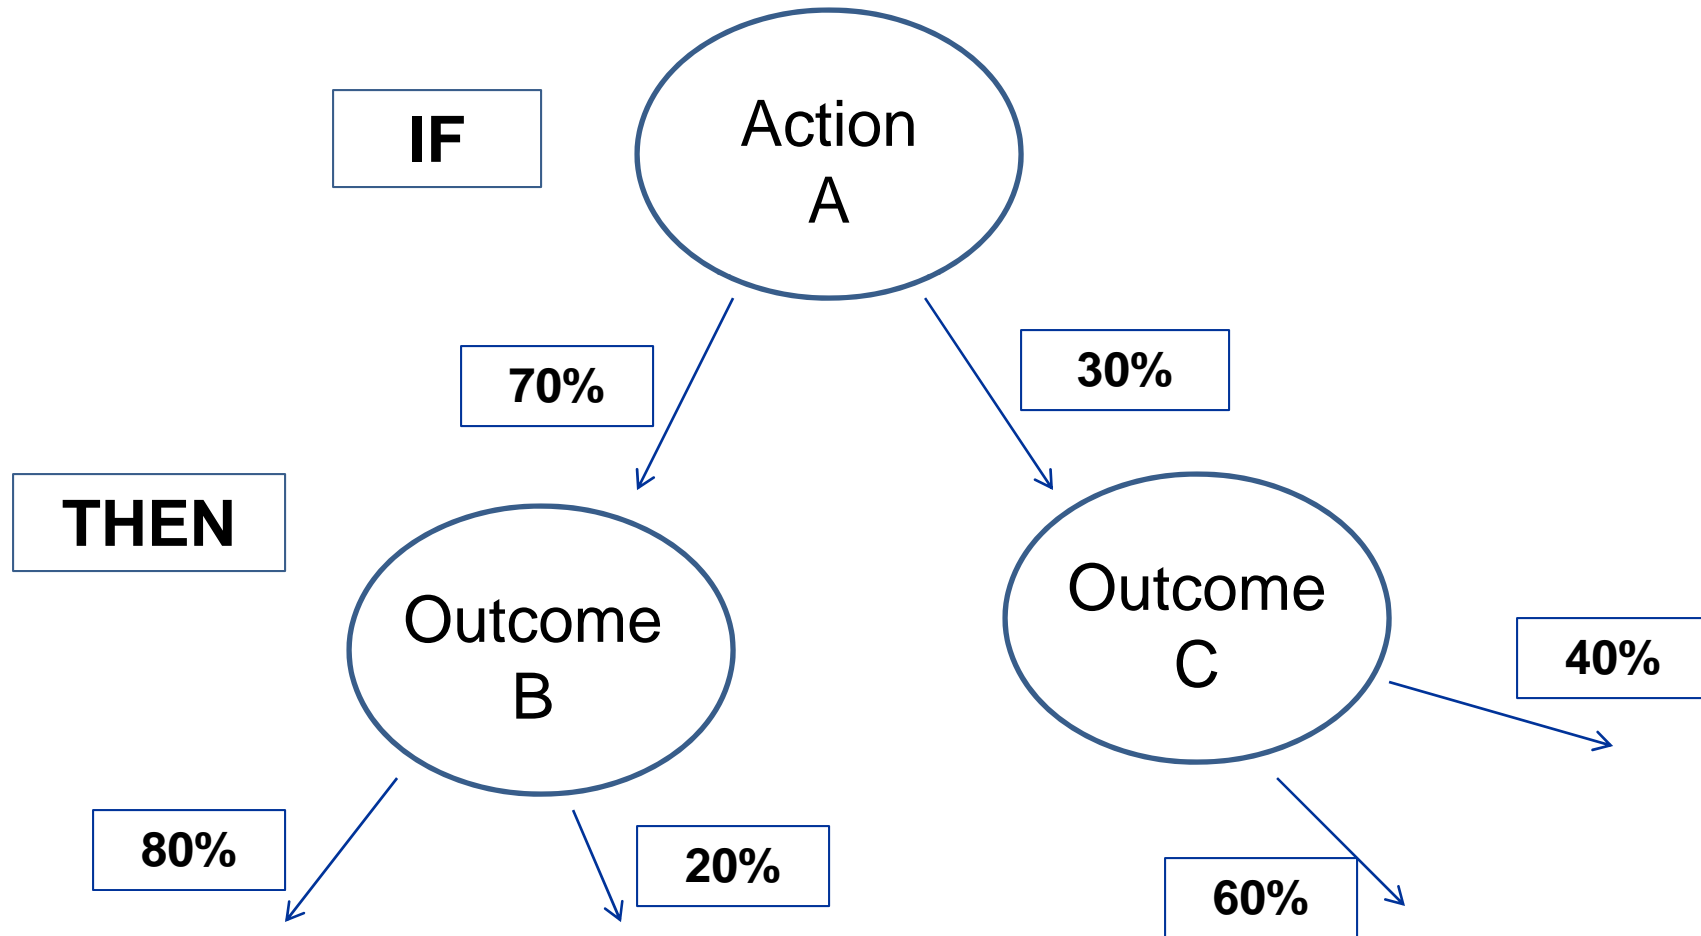

# Examples of Holistic Methods

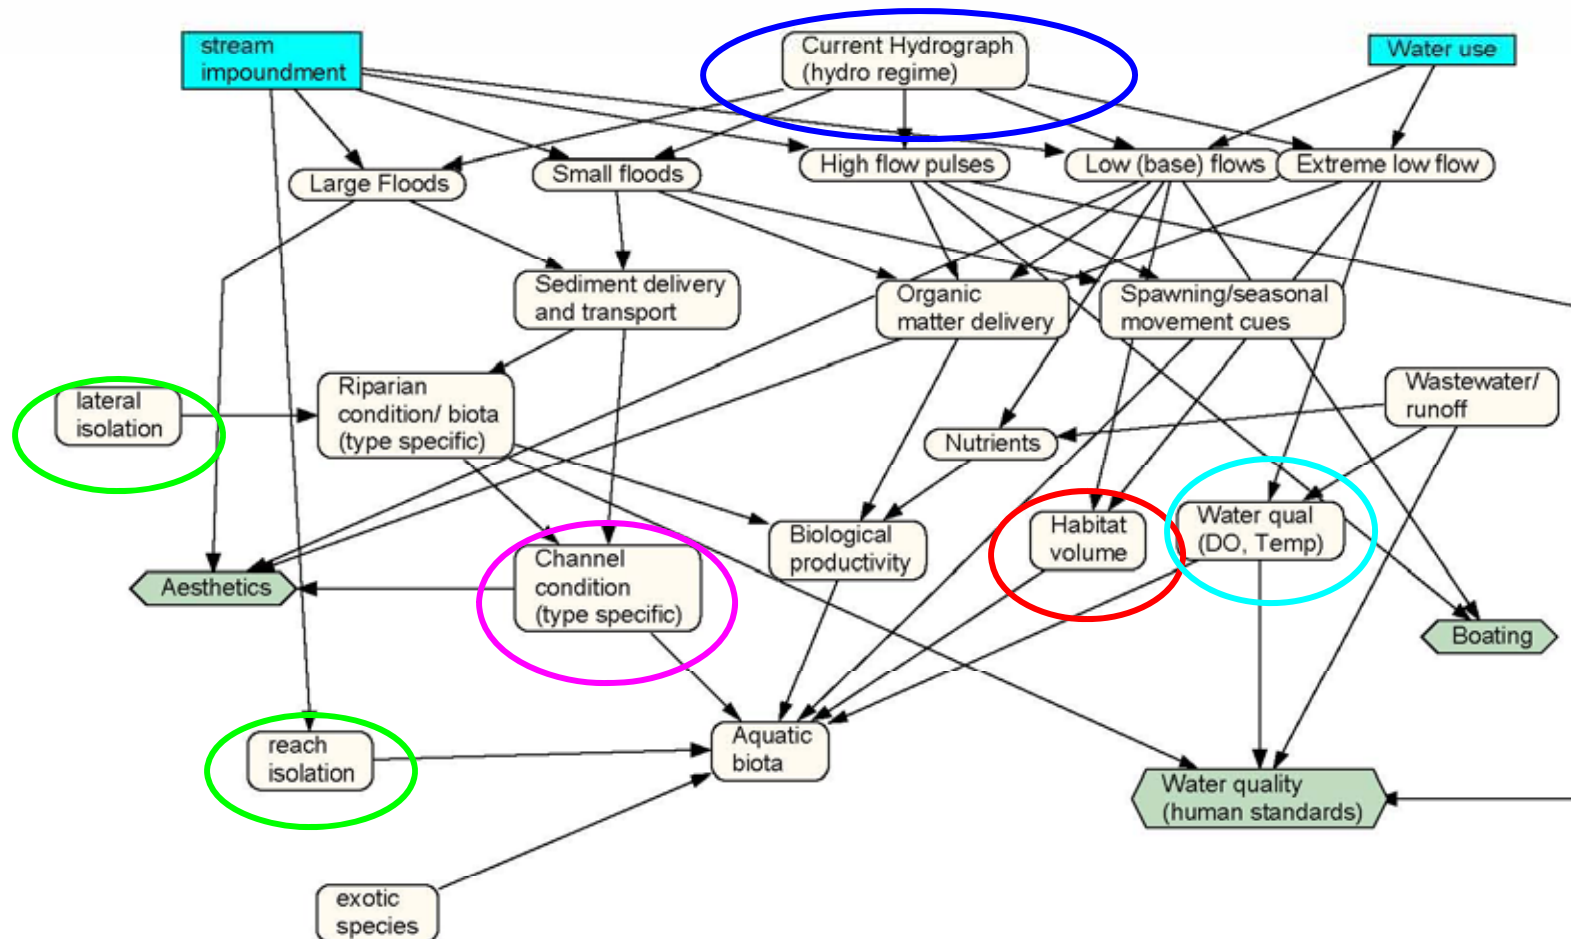

- Downstream Response to Imposed Flow Transformation (DRIFT)
- Decision Flow Assessment (DFA)
- Bayesian Probability Models
- Ecological Limits of Hydrologic Alteration (ELOHA)

# Bayesian Probability Models

# Even simple ecosystem modeling can be complicated

# Holistic Model Considerations

- Still address limited range of elements
- Outcomes are still imprecise
- Research is focused here

# Challenges and Opportunities

**IFC's Instream Flow Program Initiative**

*[www.instreamflowcouncil.org](http://www.instreamflowcouncil.org)*

# Instream Flow Program Initiative (2006-2008)

- Participants = state and provincial (Canada) fish & wildlife agencies
- Funded with federal multi-state grant
- 50 states and 6 provinces participated

# Top resources for states to address instream flow needs:

- More supportive state laws and policies
- More institutional capacity  
(agency staff, budgets, & training)
- More knowledgeable and active public

*Not more or better scientific methods*

# Instream Flow Status in Western States\*

Alaska  
Colorado  
Washington  
Oregon  
Montana  
Wyoming  
California  
Hawaii  
Idaho  
Utah  
Arizona  
New Mexico

*\* - Based on institutional capacity, legal authority, public involvement, and protected streams as judged by survey participants in 2008; ranking may differ now*

# So What?

- Avoid rhetoric – Focus on realistic issues.
- Be specific – Water in the creek? Water rights? Water management?
- Talk flow regimes – not minimum flows.
- Define the goal – protection or restoration?

# Use the Right Tool(s)

*Long-term persistence of organisms comes from long-term persistence of habitat*

# Instream Flow Laws are an Important State Tool

- Affirm state rights & control over water
  - Manage water for ESA, TMDL, Hydro, and Wild and Scenic Rivers with state law versus federal law
- Maximize ecosystem services / public benefits
  - Maintain important fisheries, recreation, water quality
  - Mitigate aquatic impacts from new dams
- Add flexibility & value to private water rights
  - Allow temporary change of use / encourage conservation

**The maximum value of water is achieved by developing an integrated system of water management that recognizes the full range of public benefits from extractive uses as well as environmental flows. *(Richter 2009)***
